

Deep Learning

AlejandroMllo

This document serves as a very brief summary of the topics covered in each chapter of the book Deep Learning [1].

Disclaimer: This document is completely extracted from [1], the author does not attribute any ownership over the material.

1 Introduction

- Deep Learning (DL) learns complicated concepts by building them out of simpler ones. DL is the study of models composed of either learned functions or learned concepts.
- Data Representation is key when finding patterns.
- Many AI tasks can be solved by designing the right set of features to extract.
- **Representation Learning:** discovers the mapping from representation to output and the representation itself.
 - Makes use of an *Autoencoder* which is a combination of:
 - * Encoder: Converts the input data into a different representation.
 - * Decoder: Converts the new representation back into the original format.
- Factors: sources of influence in the model.
- **Depth**, in a DL model, enables the computer to learn a multistep computer program (not all the information in a layer's activations necessarily encodes factors that explain the input). There are two ways to measure it:
 - Based on the number of sequential instructions, or
 - Based on the depth of the graph describing how concepts are related to each other (used by deep probabilistic models).
- DL is not an attempt to simulate the brain. It borrows ideas from different fields (one of which is neuroscience).
